

ABSTRACT

A water distributor includes a housing having an inlet for receiving water, and having two or more openings formed in a peripheral wall, for coupling to two or more water outlet members.

- 5 A valve member is rotatably received in the housing, and includes an orifice to receive the water, and a side aperture for selectively aligning with either of the openings of the housing, and to allow the water to flow out through either of the water outlet members. The valve member includes a spring-biased plug to engage with the
- 10 housing. An anchor member may be attached to the housing, to rotatably retain the valve member in the housing.
